Drawing on the resource-based view and the literature on big data analytics (BDA), information system (IS) success and the business value of information technology (IT), this study proposes a big data analytics capability (BDAC) model. The study extends the above research streams by examining the direct effects of BDAC on firm performance (FPER), as well as the mediating effects of process-oriented dynamic capabilities (PODC) on the relationship between BDAC and FPER. To test our proposed research model, we used an online survey to collect data from 297 Chinese IT managers and business analysts with big data and business analytic experience. The findings confirm the value of the entanglement conceptualization of the hierarchical BDAC model, which has both direct and indirect impacts on FPER. The results also confirm the strong mediating role of PODC in improving insights and enhancing FPER. Finally, implications for practice and research are discussed.

1. Introduction

Big data analytics (BDA) is emerging as a hot topic among scholars and practitioners. BDA is defined as a holistic approach to managing, processing and analyzing the 5 V data-related dimensions (i.e., volume, variety, velocity, veracity and value) to create actionable ideas for delivering sustained value, measuring performance and establishing competitive advantages (Fosso, Akter, Edwards, Chopin, & Gnanzou, 2015).

Yet prior studies of the business value derived from information systems (IS) investments have reported mixed results, resulting in the so-called ‘IT productive paradox’. Indeed, some scholars have argued that IS investments do not necessarily lead to improved operational efficiency and effectiveness (Irani, 2010; Roach et al., 1987; Sharif & Irani, 2006; Solow, 1987; Strassmann, 1990), while others identified a positive association between IS investments and firm performance (Barua, Konana, Whinston, & Yin, 2004; Barua, Kriebel, & Mukhopadhyay, 1995; Brynjolfsson & Yang, 1996). Their findings suggest that the absence of a positive link between IS investment and firm performance found by prior studies may be explained by several factors including the unavailability of appropriate data, the existence of time lags between IS investments and the business value generated from these investments, the absence of an assessment of the indirect benefits of IT, and the level of analysis of IS-related benefits (Anand, Fosso, & Sharma, 2013; Brynjolfsson & Hitt, 2000; Brynjolfsson & Yang, 1996; Devaraj & Kohli, 2003; Irani, 2002; Irani, Ghoneim, & Love, 2006). In fact, within this stream of research, eminent scholars argue that the impact of IT on firm performance may be mediated by a number of intermediate variables (Mooney, Gurbaxani, & Kraemer, 1996). Furthermore, they propose applying a broader view of IT resources by integrating a multidimensional perspective into studies of the business value of IT or IT capabilities (Bharadwaj, 2000; Bhatt & Grover, 2005; Santhanam & Hartono, 2003).

In this paper, we extend this stream of research by
examining factors that contribute to improved firm performance as a result of BDA investments. More specifically, the study aims to examine the following research questions:

i. How are BDA capabilities measured and are their overall uses linked with firm performance?

ii. Do process-oriented dynamic capabilities (PODC) play a mediating role in the relationship between BDAC and FPER?

To address these research questions, this research draws on the emerging literature on BDA, IT capabilities as well as the resource-based view (RBV). The remainder of this paper is structured as follows: First, definitions of big data analytics are provided. This is followed by the presentation of selected studies on IT capabilities and big data analytics capabilities. Then, the research model and our research hypotheses are presented, followed by the research design. The subsequent sections present the data analysis and findings of the study, the discussion, and the conclusion and implications for research and practice.

2. Big data analytics as a new enabler of competitive advantage

BDA is now considered as a game changer enabling improved business efficiency and effectiveness because of its high operational and strategic potential. The emerging literature on BDA has identified a positive relationship between the deployment of customer analytics and firm performance (Germann, Lilien, Fiedler, & Kraus, 2014). For example, BDA allows firms to analyze and manage strategy through a data lens (Brands, 2014). Indeed, BDA is increasingly becoming a crucial component of decision-making processes in businesses (Hagel, 2015). BDA is now considered as “a major differentiator between high-performing and low-performing organizations,” as it allows firms to become proactive and forward-looking, decreases customer acquisition costs by about 47% and enhances firm revenue by about 8% (Liu, 2014). The literature provides the example of Target Corporation, which uses BDA through its loyalty card program to track customers’ purchasing behaviors and predict their future buying trends. Amazon.com is another example of a firm that is capitalizing on BDA. Indeed, almost 35% of purchases made on Amazon.com are generated from personalized purchase recommendations to customers based on BDA (Wills, 2014). Another example discussed in the literature is GE, which is planning to use BDA to improve the efficiency of the 1500 gas turbines it monitors by means of software and network optimization, as well as to improve the dispatching of service and the coordination of gas and power systems. If realized, these benefits could lead to $66 billion in fuel savings over the next 15 years (Ward, 2014).

BDA is expected to have tremendous impacts within a variety of industries. For example, major retailing firms are presently leveraging big data capabilities to improve the customer experience, reduce fraud, and make just-in-time recommendations (Tweney, 2013). In the healthcare sector, BDA is expected to reduce operational costs and improve the quality of life (Liu, 2014). In manufacturing and operations management, BDA is considered to be an enabler of asset and business process monitoring (Davenport et al., 2012), supply chain visibility, enhanced manufacturing and industrial automation (Wilkins, 2013), and improved business transformation (Gardner, 2013).

3. IT capabilities and big data analytics capabilities

Eminent scholars argue that it is important to take a broader view of IT to better capture the business value of IS investments and deal with the IT ‘productive paradox’ (Bharadwaj, 2000; Bhatt & Grover, 2005; Santhanam & Hartono, 2003). They suggest focusing on IT capability, which is defined as the “firm’s ability to mobilize and deploy IT-based resources in combination or co-present with other resources and capabilities” (Bharadwaj, 2000). Studies on IT capability have commonly used the RBV (Bharadwaj, 2000; Santhanam & Hartono, 2003), which originated from strategic management (Ryu & Lee, 2013; Zee & Jong, 1999). In this stream of research, studies argue that competitive advantage is achieved by deploying and using distinctive, valuable, and inimitable resources and capabilities (Bhatt & Grover, 2005). In fact, the concept of IT capability is based on the assumption that, while resources can easily be replicated, a distinctive set of capabilities mobilized by a firm is not easy to replicate and will lead to sustained competitive advantages (Santhanam & Hartono, 2003). Strategic management scholars argue that “investments into different IT assets are guided by firms’ strategies and deliver value along performance dimensions consistent with their strategic purpose” (p.763) (Aral & Weill, 2007). For this stream of research, IT capability will be used to achieve strategic integration by applying the capability for IT functionality to both shape and support business strategy (Zee & Jong, 1999). Moreover, any original capability will always lead to sustained competitive advantage through its path dependency, causal ambiguity, and social complexity (Porter & Millar, 1985). Consistent with prior studies (Davenport, 2006; Davenport & Harris, 2007; Goes, 2014; McAfee & Brynjolfsson, 2012b), we view BDAC as an important organizational capability leading to sustainable competitive advantage in the big data environment. The study also argues that original capability will always lead to sustained competitive advantage through its path dependency, causal ambiguity, and social complexity (Porter & Millar, 1985). Consistent with several earlier studies (Davenport, 2006; Davenport & Harris, 2007; Goes, 2014; McAfee & Brynjolfsson, 2012b), in this study, we view BDAC as an important organizational capability leading to sustainable competitive advantage in the big data environment.

Many typologies of IT capabilities have been proposed. For example, Bhatt and Grover (2005) characterized IT capability through value, heterogeneity, and imperfect mobility. They argued that IT capability value and heterogeneity are “necessary conditions for competitive advantage,” while imperfect mobility is “necessary for sustained advantage” (p. 258). They further conceptualized three different types of capabilities: value capability (e.g., quality of IT infrastructure), competitive capability (e.g., quality of IT business expertise), and dynamic capability (e.g., intensity of organizational learning) in order to better understand the sources of IT-based competitive advantage. Using a sociomaterialistic perspective in conceptualizing a firm’s IT capability, Kim, Shin, and Kwon (2012) considered IT capability to be a function of IT management capability, IT personnel capability and IT infrastructure capability. They argued that sociomaterialism-based modeling underscores complementarities among the three IT capabilities identified, as opposed to the dominant traditional approaches in IS, in which IT capability was characterized in terms of “unidirectional and unrelated conceptualization” (p. 329). The authors also tested and found a positive relationship between IT capability and firm performance (business process and financial). This result is consistent with prior studies that assessed the relationship between IT capability and related outcomes (e.g., firm performance, firm agility, stock market returns) (Gibb, Thornley, Ferguson, & Weckert, 2011; Lin, 2007).

In a similar spirit to the IT capabilities literature, we conducted a review on big data analytics capabilities which presents us with three predominant dimensions, that is, management, infrastructure and personnel capabilities. For instance, McAfee and Brynjolfsson (2012b) put forward personnel management, technology infrastructure, and corporate decision making as critical capabilities across organizations in data economy. Similarly, Kiron, Prentice, and Ferguson (2014) identify organization culture, analytics platform, and employees’ analytics skills as core dimensions of BDA. Furthermore, Davenport et al. (2012) highlight that management, people and technology dimensions are interlinked in big data environment, which help each other to enhance broader firm performance. These dimensions of BDA and their relationships are supported by Barton and Court (2012) who point out that management capability is important to optimize decision models; technology capability is essential to explore and manage variety of data; and
finally, data science capability is important to understand, develop, and apply analytics models.

4. Research model and research hypotheses

Drawing on the emerging literature on BDA capabilities and IT capabilities, this study proposes the research model shown in Fig. 1 using RBV and sociomaterialism theory. Contrary to the literature on IT capabilities (e.g., Kim et al., 2011), this study proposes BDA capabilities as a third-order, hierarchical model manifested in three second-order constructs – BDA infrastructure capability, management capability, and personnel capability – and eleven first-order constructs: BDA planning, investment, coordination, control, connectivity, compatibility, modularity, technical knowledge, technology management knowledge, business knowledge and relational knowledge (see Fig. 1). The study also argues that BDA capabilities have a significant impact on PODEC, which in turn influences FPER.

Drawing on the RBV (Grant, 1991), relational sociomaterialism (Kim et al., 2012; Orlikowski, 2007; Orlikowski & Scott, 2008), process-oriented dynamic capabilities, and the emerging literature on BDA (Barton & Court, 2012; Davenport et al., 2012; Davenport & Harris, 2007; Kiron et al., 2014; Mcafee & Brynjolfsson, 2012a), this study proposes an ‘entanglement’ view of BDAC that has multiple complementary dimensions that synergistically allow unique firm performance to be achieved (Clemons & ROW, 1991; Kim et al., 2012; Powell & Dent-Micalef, 1997; Tippins & Sohi, 2003) (Fig. 1). Similar to (Kim et al., 2012), we argue that BDA infrastructure capability, personnel capability and management capability are the key components of a firm’s BDAC (see Table 1).

Prior studies have identified a positive link between IT capability and firm outcomes. For example, (Lu & Ramamurthy, 2011, p. 931), using a matched-pair field survey of business and information systems executives in 128 organizations, identified a significant positive relationship between IT capability and two types of organizational agility: market capitalizing agility and operational adjustment agility. Similarly, on the basis of matched survey data collected from 214 Chinese IT and business executives from manufacturing firms, (Chen et al., 2014) found that IT capability has a positive effect on firm performance. They also found that dynamic capability of the business process mediates the relationship between IT capability and firm performance. Using a cross-sectional sample of 155 banking firms, (Lin, 2007, p. 93) showed that IT capability and human capital investment “contribute directly to the

</table>
overall value-creation performance of banking firms". (Kim et al., 2012) applied a relational sociomaterialistic conceptualization of IT capability and found a positive and significant relationship between IT capability and a firm’s performance. Based on this observation, our study suggests testing not only the direct effects of BDAC on FPER but also the mediating effects of PODC on the relationship between BDAC and FPER (Fig. 1).

Therefore, we put forward the following hypotheses:

**H1.** BDAC has a significant positive effect on PODC.

**H2.** BDAC has a significant positive effect on FPER.

**H3.** BDAC has a significant positive indirect effect on FPER, which is mediated by a positive effect on PODC.

5. Research method

The study is based on positivist research approach assuming that the world of phenomena has an objective reality which can be expressed in causal relationships and measured in data (Straub, Boudreau, & Gefen, 2004). Using the positivist approach, the study captured the objective and social reality by survey measures to identify the BDA capabilities in order to address the research questions. As part of this approach, we initially explored literature to identify the dimensions of BDA capabilities, their overall impact on firm performance and the mediating role PODC between BDAC and FPER. Based on RBV and sociomaterialism theory, we conceptualized the research model, developed the survey and validated the hypothesized relationships using partial least squares (PLS) based structural equation modeling (SEM).

5.1. Survey, scaling and sampling

This study adopted the questionnaire based survey method because it captures causal relationships between constructs and hence provides generalizable statements on the research setting (Pinsonneault & Kraemer, 1993). Moreover, surveys can accurately document the norm, identify extreme information and delineate associations between variables in a sample (Gable, 1994). Straub et al. (2004) also recommended survey research for explanatory and predictive theory in order to ensure greater confidence in the generalizability of the results.

The survey questionnaire used in the study consists of previously published multi-item scales with favorable psychometric properties (see Table 3). All the constructs in the model were measured using 7-point Likert scales (strongly disagree – strongly agree). A cross-sectional survey was used to collect the data and test the research model.

The data collection consisted of three steps. Before the main survey, a pilot study was conducted to ensure that the measures were valid and reliable. The questionnaires were distributed to on-the-job postgraduate students in the Master of Engineering program in one of the leading Chinese universities. Among them only those who had big data and business analytics experiences were invited to fill in the questionnaire. 42 usable questionnaires were collected and the measures ensured good reliability and validity. The final items used in the questionnaire and their sources are listed in Table 3.

We collected data from China as one of the most active areas in e-commerce and m-commerce development and the online markets of China account around for 60% of retail in Asia (Harca, 2015). This is a hugely significant retail market that attracts scholars and practitioners because of the wealth of data gathered. Chinese practitioners have opportunities to pin it down and make the data useful; however these practices are not limited to China alone; it can be used for other countries. By designing the study on the general capabilities that these practitioners need to have in big data analytics and avoiding culture-sensitive concepts, we believe our data has generalisability to other countries.

The main survey was conducted by a market research firm with a database of more than 10,000 Chinese IT managers and business analysts. There are two reasons why we choose this market firm: 1) it has the resource of a large list of more than 10,000 Chinese IT managers and business analysts, 2) it has a professional reputation for its survey quality control. An online questionnaire was distributed to 500 people using simple random sampling. In around two weeks, we received responses from 315 people. Due to the online nature of the data collection, the study did not provide any missing values because respondents were not allowed to proceed to the next question if they did not answer a particular question. However, this option resulted into 20 incomplete answers and the study excluded those responses from the dataset. We also excluded those responses from the study that were provided by managers without any big data and business analytic experience. After these procedures, 225 questionnaires were usable. To collect more data, we asked the market research firm to distribute the survey to another 200 people, and 90 more responses were received. In the end, there were 297 usable questionnaires. Of the respondents, 77.7% were male, and the majority (more than 86%) had a college qualification or above. Table 2 represents the respondents’ demographic characteristics and the characteristics of their firms.

6. Confirmatory factor analysis using PLS-SEM

In order to assess the higher-order BDA capabilities model, the study applied partial least squares based structural equation modeling (PLS-SEM) because it estimates hierarchical models by removing the uncertainty of inadmissible solutions using its flexible assumptions (Hair, Ringle, & Sarstedt, 2011; Hulland, Ryan, & Rayner, 2010). We applied PLS-SEM because it ensures greater theoretical parsimony and less model complexity to estimate the hierarchical model (Edwards, 2001; Wetzels, Odekerken-Schroder, & Van Oppen, 2009). For instance,

</table>
using PLS path modeling. Wetzels et al. (2009) recently developed a fourth-order, hierarchical-reflective model of online experiential value to predict e-loyalty. Hierarchical modeling can be done in two different ways depending on the relationship between latent variables and manifest variables: hierarchical-reflective modeling and hierarchical-formative modeling. In the reflective model, the latent variables affect the manifest variables (LVs → MVs), whereas in the formative model, the manifest variables affect the latent variables (MVs → LVs). The reflective construct is generally viewed as giving rise to its indicators (Fornell & Bookstein, 1982), but the formative construct views its indicators as defining characteristics. Based on the established guidelines on hierarchical modeling (Akter, D’Ambra, & Ray, 2010; Becker, Klein, & Wetzels, 2012; Wetzels et al., 2009), the study applied PLS-SEM to estimate the third-order, reflective BDA capabilities model.

6.1. Measurement model

In order to assess the hierarchical research model, we used PLS Graph 3.0 (Chin, 2001) to estimate the parameters in the outer and inner models. In this case, we applied PLS-SEM with a path weighting scheme for the inside approximation. Then we applied nonparametric bootstrapping (Chin, 2010b; Efron & Tibshirani, 1993) with 5000 replications to obtain the standard errors of the estimates (Hair, Hult, Anderson, & Black, 2006), suggesting that multicollinearity, collinearity diagnostics for constructs were also conducted. The analysis shows that the collinearity indicator (variance inflation factor) falls below the acceptable cut-off point (VIF < 5) (Hair, Tatham, Anderson, & Black, 2006), suggesting that multicollinearity is not an issue in our study. Finally, we estimated the goodness-of-fit ($R^2$) following Tenenhaus, Vinzi, Chatelin, and Lauro (2005) for PLS path modeling and the results show that the model has adequate goodness-of-fit as it exceeds the 0.36 suggested by Wetzels et al. (2009).

6.2. Structural model

The structural model indicates that BDAC and PODC enhanced FPER, with path coefficients of 0.56 ($p < 0.001$) and 0.28 ($p < 0.01$) respectively, explaining 65% of the variance. BDAC enhanced PODC, with a path coefficient of 0.84 ($p < 0.001$), explaining 70% of the variance. Thus, all three hypotheses, H1 to H3, were supported as the path coefficients were significant at $p < 0.001$. In sum, the $R^2$ scores for all dependent variables (PPER: 65%; PODC: 70%) explained by the research model were significantly large according to the effect sizes defined for $R^2$ by Cohen (1988) and Chin (2010b).

6.3. Test for mediating effects

Our proposed research model includes potential mediation effects. Specifically, PODC may mediate the impact of BDAC on FPER. The procedure for mediation analysis is based on the path coefficients and standard errors of the direct paths between (i) independent and mediating variables (i.e., iv → m), and (ii) mediating and dependent variables (i.e., m → dv). The results of the PLS analysis are used to calculate the extent to which a construct mediates the relationship between the independent variable and the dependent variable (Hoyle and Kenny, 1999). In this study, the magnitude of the mediation effect between BDAC (iv) and FPER (dv) mediated by PODC (m) is the product
of the standardized paths between iv and m and between m and dv. The standard deviation of the mediated path can be computed based on the magnitudes and the variance of the paths among iv, m, and dv. The results of the analyses of paths in the model are shown in Table 6. The results showed that PODC mediated BDAC and FPER with a z-statistic of 3.19 using the Sobel test.

7. Conclusions

The primary objective of this study was to examine the direct impact of BDAC on FPER, as well as the mediating effects of PODC on the relationship between BDAC and FPER. The results show that all the causal links posited by our model are supported. More specifically, both BDAC and PODC explain 65% of the variance of FPER in which 30% of the variance is explained by the mediator. The study estimated the size of the indirect effect using variance accounted for (VAF) value, which indicates the ratio of the indirect effect to the total effect (0.84 + 0.28/0.84 + 0.28 + 0.56). The findings show that the higher-order BDAC construct has a stronger effect on FPER than the PODC. However, PODC appears to be a significant partial mediator, which suggests improving both BDAC and PODC in order to enhance FPER. Among all the dimensions of BDAC, infrastructure and personnel capabilities (β = 0.96) were relatively more important than management capability (β = 0.93). Although we identified these differences in measuring the importance of BDAC dimensions, we note that differences are very small, thus all the dimensions should be given equal importance in building BDAC. The findings also show that second-order constructs have significant positive association with their corresponding first order components. For instance, infrastructure capability was reflected by connectivity (β = 0.90), compatibility (β = 0.90) and modularity (β = 0.92) in which modularity reflects the highest variance (85%) of infrastructure capability. Accordingly, variance of management capability and personnel capability were calculated to reflect their corresponding components (Fig. 2). Overall, the nomological validity of the study was ensured as the findings show that BDAC has a significant positive impact on both PODC (R² = 0.70) and FPER (R² = 0.65) in which PODC was recognized as a strong mediator.

7.1. Implications for research

This study has several theoretical implications for BDAC research. First of all, it is among the first studies to assess the impact of BDAC on firm performance and process-oriented dynamic capabilities and evaluate the mediation effect of PODC on the relationship between BDAC and FPER. Although there is a rich body of literature on BDAC (Kim et al., 2012) and PODC (Kim et al., 2011), research on integration of the two constructs is scant. The role of BDAC on FPER emerges clearly from the previous literature. What is less understood is the mediating effect of PODC on BDAC’s impact on FPER. Hence, our study tested the mediating effect on BDAC and FPER using data gathered from Chinese firms. This study also integrates BDAC and PODC in a single model and reconciles what had previously been assumed to be independent constructs. In the existing literature, the combined effects of BDAC and PODC have rarely been studied. Finally, by adopting the approach of decomposing BDAC into three constructs, as shown in the theoretical model (Fig. 1), we show that this method helps to understand the linkage between BDAC and FPER.

7.2. Implications for practice

Many of our findings provide guidance to managers and consultants who are engaged in implementing BDAC in firms. The mediating role of PODC clearly highlights how, in uncertain environments, BDAC can be leveraged as a source of sustainable competitive advantage. Conversely, if PODC is missing, then BDAC, which may be effective in the present scenario, can lose its competitive advantage, given that the business environment is highly dynamic in nature. The finding that the three BDAC components strongly influence firms’ performance indicates that, in order to translate BDAC into firm performance, managers need to concentrate on infrastructure capability, which includes BDA connectivity, compatibility and modularity. Similarly, managers may examine the microstructure of BDA planning, investment, coordination and control. This helps to ensure BDA management capability, which is one of the pillars of BDAC. Finally, the most important pillar of BDAC is BDA personnel expertise capability. To strengthen this aspect of BDAC, an organized effort must be made to build technical knowledge, technological management knowledge, business knowledge and relational

knowledge related to BDA. We recognize that the idea of recommending that organizations embrace the three-pillar strategy of BDAC may sound highly theoretical. However, this conclusion is based on our findings from the data.

7.3. Limitations and future research

We believe that our model is sound and firmly grounded in theory and we have tested it with reliable survey instruments and data.

Statistic is significant at **p < 0.01.
The standard error of the mediated path is approximated based on the formula sqrt(b^2 S_a^2 + a^2 S_b^2 + S_a^2 S_b^2), where a and b are the magnitudes of the paths between iv, m, and dv, and S_a and S_b are the standard deviations of a and b.

Nevertheless, some limitations and unanswered questions must be addressed. First, we conducted the study within the specific domain of big data analytics and in one context. Although BDA by its nature is context-specific due to the variations in analytics industry, replications of the conceptual model in other settings would enhance its generalizability.

Second, we tested our model using cross-sectional data, thus we recommend retesting the findings using panel data to investigate its stability. Third, in our study we adopted perceptual performance measures, which could be replaced by objective measures to present a concrete picture of BDAC’s impact on firm performance. Fourth, we recommend developing context specific BDAC instrument (e.g., customer analytics, supply chain analytics etc.) through rigorous scale validation procedure in order to better measure BDAC for various industries. Finally, we did not investigate the impact of organizational culture and top management commitment on the implementation of BDAC in a firm, which could be taken into account as moderating variables to extend knowledge in the big data economy.
